mTOR Mediates IL-23 Induction of Neutrophil IL-17 and IL-22 Production

Feidi Chen,* Anthony Cao,[†] Suxia Yao,[†] Heather L. Evans-Marin,[†] Han Liu,^{†,‡} Wei Wu,^{†,§} Eric D. Carlsen,^{†,¶} Sara M. Dann,[¶] Lynn Soong,^{*,†} Jiaren Sun,[†] Qihong Zhao,[¶] and Yingzi Cong^{*,†}

It has been shown recently that neutrophils are able to produce IL-22 and IL-17, which differentially regulate the pathogenesis of inflammatory bowel disease. However, it is still largely unknown how the neutrophil production of IL-22 and IL-17 is regulated, and their role in the pathogenesis of inflammatory bowel disease. In this study, we found that IL-23 promoted neutrophil production of IL-17 and IL-22. IL-23 stimulated the neutrophil expression of IL-23R as well as *rorc* and *ahr*. Retinoid acid receptor–related orphan receptor γ t and aryl-hydrocarbon receptor differentially regulated IL-23 induction of neutrophil IL-17 and IL-22. In addition, IL-23 induced the activation of mTOR in neutrophils. Blockade of the mTOR pathway inhibited IL-23–induced expression of *rorc* and *ahr*, as well as IL-17 and IL-22 production. By using a microbiota Ag-specific T cell–mediated colitis model, we demonstrated that depletion of neutrophils, as well as blockade of IL-22, resulted in a significant increase in the severity of colitis, thereby indicating a protective role of neutrophils and IL-22 in chronic colitis. Collectively, our data revealed that neutrophils negatively regulate microbiota Ag-specific T cell induction of colitis, and IL-23 induces neutrophil production of IL-22 and IL-17 through induction of *rorc* and *ahr*, which is mediated by the mTOR pathway. *The Journal of Immunology*, 2016, 196: 4390–4399.

Inflammatory bowel disease (IBD), which includes ulcerative colitis and Crohn's disease, represents chronic or recurring inflammation in the gastrointestinal tract. The pathogenesis of IBD is considered multifactorial, involving compromise of the intestinal epithelial barrier and dysregulation of immune responses to commensal bacteria (1). As an essential component of the innate immune system, neutrophils are implicated in the pathogenesis of IBD by virtue of the high neutrophilic influx in the inflamed intestinal tissue of IBD patients (2). Emerging evidence highlights the greater value of neutrophil-derived products such as fecal calprotectin (S100A8/S100A9) than the traditional inflammatory marker C-reactive protein in the assessment of disease activity in

clinical practice (3-5). Although intense efforts have been made to elucidate the role of neutrophils in IBD, conflicting data have been reported in different animal models that mimic IBD. In the dextran sodium sulfate (DSS)-induced colitis model, the ablation of neutrophils accentuated colitis, likely indicating a potential beneficial role of neutrophils (4). Furthermore, the mice with chronic granulomatous disease contain neutrophils with impaired functions, and these mice showed poor inflammatory resolution and succumbed rapidly during trinitrobenzene sulfonic acid-induced colitis (6, 7). This finding has been elaborated as a protective function of neutrophils by generating the "inflammatory hypoxia" microenvironment in the inflamed tissue as a way to promote intestinal epithelial healing through HIF-1 induction (8). In contrast, it has also been reported that specific inhibition of neutrophils by mAb attenuates DSS-induced colitis in rats (6), and the influx of neutrophils into the intestines leads to massive migration of neutrophils across intestinal epithelium into the intestinal lumen, thereby weakening the cell-tocell junctions and increasing epithelial permeability, which results in subsequent bacteria translocation and water influx that worsens inflammation (9, 10). Notably, all animal models used in previous reports were acute colitis models, that is, DSS- or trinitrobenzene sulfonic acid-induced colitis; thus, it is still unclear how neutrophils regulate chronic colitis with characteristics like those found in human patients with IBD.

Recently, neutrophils have been identified as an important source of both IL-17 and IL-22 (9, 11). IL-22, a member of the IL-10 cytokine family, specifically targets epithelial cells based on the expression pattern of the IL-22R (10). IL-22 has been shown to promote barrier defense and wound healing by inducing intestinal epithelial cell secretion of antimicrobial proteins, epithelial cell differentiation, and goblet cell activation (12). IL-17 is a critical component of mucosal immune defense (13, 14). Although detrimental effects of IL-17 have been implied during colitis (15, 16), its protective function has also been demonstrated recently (17, 18). Notably, IL-22–producing neutrophils are reported protective

Abbreviations used in this article: AhR, aryl-hydrocarbon receptor; B6, C57BL/6; BM, bone marrow; CBir1-Tg, CBir1 flagellin-specific TCR-transgenic; DSS, dextran sodium sulfate; Hnf4 α , hepatocyte NF 4 α ; IBD, inflammatory bowel disease; ILC, innate lymphoid cell; LB, large bowel; MDSC, myeloid-derived suppressor cell; mTOR, mammalian target of rapamycin; mTORC1, mTOR complex 1; qRT-PCR, quantitative RT-PCR; ROR γ t, retinoid acid receptor–related orphan receptor γ t; UTMB, University of Texas Medical Branch.

during acute colitis, in that colitis was alleviated in DSS-treated IL-22^{-/-} mice receiving neutrophils from wide-type mice, whereas neutrophils from IL-22^{-/-} mice exhibited little effect on disease progression (9). In contrast, IL-17–producing neutrophils aid in bactericidal defense during fungal infection (11, 19, 20). However, it is unclear how neutrophil production of IL-22 and IL-17 are regulated, and their roles in the pathogenesis of chronic colitis must yet be clarified. We report in this article that IL-23 primarily promotes neutrophil production of IL-17 and IL-22 by regulating retinoid acid receptor–related orphan receptor γ t (ROR γ t) and aryl-hydrocarbon receptor (AhR) through activation of mammalian target of rapamycin (mTOR). Furthermore, neutrophils protect the intestines from chronic intestinal inflammation, possibly by producing IL-22.

Materials and Methods

Mice

C57BL/6 (B6) mice and Rag $2^{-/-}$ mice were obtained from the Jackson Laboratory. CBir1 flagellin-specific TCR-transgenic (CBir1-Tg) mice (21) were bred in the Animal Facilities at the University of Texas Medical Branch (UTMB) and maintained there. All animal work was reviewed and approved by the Institutional Animal Care and Use Committees of the UTMB.

Abs and reagents

Neutralizing Abs to Ly6G (1A8), Thy1.2 (30H12), IFNg (XMG1.2), and IL-4 (11B11) were purchased from Bio X Cell (West Lebanon, NH). Neutralizing Ab to mouse IL-22 (8E11.9) was provided by Genentech (South San Francisco, CA). Thioglycollate broth was purchased from Sigma-Aldrich (St. Louis, MO). RORyt inhibitor was provided by Bristol Myers Squibb. AhR inhibitor CH-223191 was purchased from Sigma-Aldrich, and mTOR inhibitor rapamycin and AZD8055 from Selleck Chemicals (Houston, TX). PI3K inhibitor LY294002 was purchased from Sigma-Aldrich. STAT3 inhibitor HJC0152 was kindly provided Dr. Jia Zhou at UTMB. Abs against phosphorylated mTOR (S2448), phosphorylated 4E-BP1 (T70), phosphorylated STAT3 (P65), phosphorylated NF-KB (Y705), β-actin, and HRPconjugated anti-rabbit secondary Ab were obtained from Cell Signaling Technology (Danvers, MA) for Western blot analysis. The following Abs were used for flow cytometry: PerCP/Cy5.5-IL-17 (TC11-18H10.1), FITC-CD11b (M1/70), PE/Cy7-Ly6G (1A8) were from Biolegend (San Diego, CA). PE-IL-22 (1H8PWSR), allophycocyanin-IL-10 (JES5-16E3) were from eBioscience (San Diego, CA). Foxp3 Perm/Fix Kit for intracellular permeabilization was from eBioscience, and Live/Dead Fixable Dead Cell Stain Kit was from Life Technologies (Carlsbad, CA). GolgiStop was purchased from BD Biosciences (San Diego, CA).

Neutrophil isolation and culture

The neutrophils were prepared from the peritoneal cavity as we previously described (22). In brief, B6 mice were injected with 1 ml 3% thioglycollate broth, and the peritoneal cavity was washed with cold PBS buffer containing 5% FBS 5 h later. Neutrophils were separated from other cell types in the peritoneal exudate by using 50% Percoll (Sigma-Aldrich). Cell viability (>95%) was validated by trypan blue staining, and flow cytometry was performed to confirm neutrophil purity (>95%). For bone marrow (BM) neutrophil collection, murine femurs were obtained under aseptic conditions and flushed by cold PBS. Neutrophils were then isolated from BM cells by using anti-mouse Ly6G-magnetic sorting (Miltenyi Biotec).

Real-time quantitative RT-PCR

RNA was extracted with TRIzol (Life Technologies, Carlsbad, CA) and quantified for cDNA synthesis. Quantitative PCRs were performed by using TaqMan Gene Expression Assays (Life Technologies). Predesigned primers and probes for *ill7* (Mm00439618_m1), *ill2* (Mm00444241_m1), *rorc* (Mm01261022_m1), *ahr* (Mm00478932_m1), *hepatocyte NF* 4 α (*Hnf*4 α) (Mm01247712_m1), and *gapdh* (Mm99999915_g1) were purchased from Applied Biosystems, and data were normalized to *gapdh* mRNA expression. Aliquots of PCR products were visualized under UV by electrophoresis on 1.5% agarose gels.

Induction of colitis

CD4⁺ T cells were isolated from the spleens of CBir1-Tg mice by using anti-mouse CD4-magnetic beads (BD Biosciences) as previously described (23). To generate Th17 cells, we cultured 0.2×10^6 CD4⁺ CBir1-Tg T cells with the same number of irradiated splenocytes in the presence

of 10 ng/ml TGF- β 1, 20 ng/ml IL-6, 10 µg/ml anti–IFN- γ (XMG1.2), and 10 µg/ml anti–IL-4 (12B11) for 5 d. The polarized Th17 cells were validated by FACS staining. Then 2 × 10⁶ Th17 cells were transferred i.v. into the recipient Rag^{-/-} mice. Mice were monitored by weight weekly and sacrificed either when body weight reached 80% of initial weight or at the end of 6 wk. As previously described (18), 2% DSS (MP Biomedicals) was administrated to Rag^{-/-} mice for 7 d, followed by 3 d of fresh water. Mice were monitored by weight daily and sacrificed either when body weight reached 80% of initial weight or at the end of day 10.

Preparation of lamina propria cells

Intestines were opened and cleaned of feces to isolate lamina propria cells. Intestines were chopped and incubated with 50 mM EDTA for 40 min. Remaining tissue was incubated with 0.5 g/ml Collagenase IV and 5 μ g/ml DNase I (Sigma-Aldrich) for two rounds of 30 min. Lamina propria cells were isolated from a 40%/75% Percoll interface.

Ex vivo colon organ culture and ELISAs

Colons were open and cleaned of fecal matter and contaminates. Then 3-mm biopsies from the ascending colon were placed into RPMI 1640 (10% FBS, HEPES, penicillin-streptomycin, 2-ME, and sodium pyruvate) (Invitrogen, Carlsbad, CA) cultured at 37°C with 5% CO₂. Supernatants were harvested after 1 d, and the concentration of cytokine was determined by ELISA as previously described (18). Mouse IL-6, IL-17(A), IL-22, TNF- α , and IFN- γ ELISA kits (BD Pharmingen, San Diego, CA) were used in this study according to the manufacturer's protocols.

Histopathological assessment

At necropsy, cecum and colon were harvested and washed with PBS. Swiss rolls were prepared. Tissues were fixed in 10% buffered formalin and embedded in paraffin. Then 5- μ m sections were sliced, stained with H&E, and histological scoring was blindly performed by an experienced pathologist using a modified scoring system reported previously (24). The scoring includes the following aspects: lesion in intestinal crypts, goblet cell condition, crypt exudate, inflammatory cell infiltration, and tissue inflammatory condition. The damages were estimated and scored from 0 to 3, representative of intensity, that is, absent, mild, moderate, or severe, respectively. The final colitis severity score was calculated by taking both intensity and extent of lesion into account.

Statistical analysis

To assess an effect of a given sample size, we performed power analysis by using preliminary data sets. For comparison between samples, levels of significance were determined by appropriate statistical analysis based on whether the data were normally distributed and the number of tested groups for comparison. All statistical analysis was performed in Prism 5.0 (GraphPad Software, San Diego, CA). Results are shown as mean \pm SEM; *p < 0.05, **p < 0.01.

Results

IL-23 stimulates neutrophil production of IL-17 and IL-22

IL-23 has been consistently shown to be able to stimulate IL-22 production in $\gamma\delta$ T cells, dendritic cells, and type 3 innate lymphoid cells (ILCs). IL-6, IL-21, TNF- α , and IL-1 β have also been able to stimulate IL-17 and/or IL-22 production at different levels in ILCs and several CD4⁺ T cell subtypes (11, 25). Although IL-23 itself induces little IL-17 or IL-22 in CD4⁺ T cells, it can greatly augment IL-17 and IL-22 production in Th17 cells (26). In a recent report, colonic neutrophils isolated from mice with DSSinduced colitis have been shown to produce both IL-17 and IL-22 after IL-23 treatment. Colon tissue of IL-23a^{-/-} mice revealed a significant decrease in IL-22 levels compared with those in widetype mice (9). However, the cytokines, which stimulate neutrophil production of IL-17 and/or IL-22, have not been carefully elucidated. The short half-life of neutrophils makes it hard to be isolated from intestines, because it requires a long processing time, and thus most neutrophils isolated would have died by the end of preparation. We thus use peritoneal neutrophils because they are ready to be prepared in large quantities in our in vitro studies (22). We stimulated peritoneal neutrophils with IL-23, IL-6, IL-21, TNF- α , or IL-1 β to assess which cytokine(s) trigger IL-17 and

IL-22 production in neutrophils. A portion of cells was stained for CD11b and Ly6G to assure that the purity of neutrophils population (CD11b⁺Ly6G⁺) is >95% (Supplemental Fig. 1). The levels of IL-17 and IL-22 in the supernatant were determined via ELISA. Consistent with a previous report, treatment with IL-23 alone markedly enhanced production of IL-17 and IL-22 at levels of both protein and mRNA (Fig. 1A, 1B). In contrast, IL-1β, IL-6, IL-21, and TNF- α had little or no effect on the production of IL-17 and IL-22 when administered either alone or in combination with IL-23 (Fig. 1A), indicating a critical role of IL-23 in inducing IL-17 and IL-22 production in neutrophils. Because recent evidence indicates that there are different subsets of neutrophils, to evaluate whether the same or different neutrophils produce IL-17 or IL-22, we used flow cytometry to identify the subsets of IL-17- and IL-22-producing neutrophils after IL-23 stimulation. As shown in Fig. 1C, increased amounts of IL-22-producing CD11b⁺ Ly6G⁺ neutrophils were found relative to untreated cells. Interestingly, we found a slightly increased number of IL-10⁺ neutrophils in the presence of IL-23.

IL-23 induces IL-23R expression on neutrophils

IL-23R mRNA has been recently found to be expressed on naive neutrophils in BM (11). Neutrophils also appear to express IL-23R after migration into the inflamed colon (9). The isolated neutrophils are more activated than those from BM after migrating from blood vessels to peritoneal cavity in response to thioglycollate, whereas BM neutrophils are naive. To understand the regulation of neutrophil IL-23R expression, we examined the expression of IL-23R in peritoneal neutrophils. As shown in Fig. 2A and 2B, IL-23R was expressed in the peritoneal neutrophils at a higher level compared with that in BM cells (Fig. 2A, 2B). The peritoneal neutrophils can further respond to stimulants and elicit a more exaggerated response. Accordingly, we found that IL-23 further stimulated IL-23R expression in the peritoneal neutrophils (Fig. 2C). Together, these data suggest that, unlike T cells, naive neutrophils constantly express a basal amount of IL-23R, and the expression of IL-23R increases as the cells become activated.

RORyt and AhR differentially regulate IL-17 and IL-22 production in neutrophils

ROR γ t is an essential transcription factor mediating IL-17 production in Th17 cells (27). Moreover, it has been shown that

FIGURE 1. IL-23 stimulates neutrophil production of IL-17 and IL-22. (A) Peritoneal neutrophils were treated with IL-1B (20 ng/ml), IL-6 (30 ng/ml), IL-21 (20 ng/ml), or TNF-a (20 ng/ml), alone or in combination with IL-23 (20 ng/ml) for 24 h. IL-17 and IL-22 production were measured from the supernatant by ELISA. (B) Neutrophils were stimulated with IL-23 for 6 h. mRNA for il17 and il22 were determined by qRT-PCR and normalized against gapdh. The relative expression of IL-17 and IL-22 untreated neutrophils was arbitrarily set to 1.0. IL-17 and IL-22 expression were compared between the IL-23treated and untreated neutrophils. *p < 0.05. Data are representative of three independent experiments. (C) Neutrophils were stimulated with IL-23 (20 ng/ml) in the presence of GolgiStop for 12 h. Cytokine expression was measured by flow cytometry. FACS plots are representative of three independent experiments. NT, no treatment.

RORyt is indispensable for IL-22 expression in ILC3 (28). The ligand-dependent transcription factor AhR also contributes to IL-17 and IL-22 expression in lymphoid cells (28-30). We then investigated whether RORyt and AhR are involved in IL-23-driven IL-17 and IL-22 production in neutrophils. As shown in Fig. 3A, addition of IL-23 upregulated expression of transcripts encoding RORyt (rorc) and AhR (ahr) in neutrophils, indicating that IL-23 is capable of inducing both transcription factors. To investigate the role of RORyt and AhR in neutrophil IL-17 and IL-22 production, we treated peritoneal neutrophils with small-molecule inhibitors against RORyt or AhR in the presence of IL-23. As shown in Fig. 3B, inhibition of RORyt compromised both IL-17 and IL-22 production in IL-23-treated neutrophils, indicating that induction of both cytokines is RORyt dependent (Fig. 3B). Interestingly, AhR inhibition only decreased IL-22 production with no detectable impact on IL-17 expression. Addition of both RORyt and AhR inhibitors further reduced IL-17 and IL-22 production, suggesting that RORyt and AhR act in a synergistic manner. Collectively, the data indicate that RORyt and AhR differentially regulate neutrophil production of IL-17 and IL-22.

mTOR regulates IL-23–driven IL-17 and IL-22 production in neutrophils

mTOR is a serine/threonine kinase that is crucial for cell growth and proliferation (31). Previous data indicate that mTOR is expressed in neutrophils and modulates neutrophil function (32); therefore, we investigated whether mTOR is involved in IL-23 induction of IL-17 and IL-22 in neutrophils. IL-23 treatment led to the phosphorylation of mTOR (Fig. 4A). In addition, 4E-BP1, a major downstream effector molecule of mTOR complex 1 (mTORC1) was also activated after the treatment of IL-23, further confirming that IL-23 activates the mTOR pathway. We then applied rapamycin, a well-established mTORC1 inhibitor to neutrophils in combination with IL-23. As expected, rapamycin greatly attenuated IL-23-induced phosphorylation of 4E-BP1 (Fig. 4B). To confirm these results, we adopted another mTOR inhibitor (AZD8055), which targets both mTORC1 and mTORC2 to neutrophils (33-35). Consistent with rapamycin, AZD8055 inhibited IL-23-induced phosphorylation of 4E-BP1 (Fig. 4B). To determine whether mTOR regulates IL-23-driven cytokine production in neutrophils, we first examined IL-17 and IL-22 gene transcription. The quantitative RT-PCR (qRT-PCR) showed markedly decreased IL-17 and IL-22

FIGURE 2. IL-23 induces IL-23R expression on neutrophils. Two micrograms RNA from freshly isolated peritoneal neutrophils and BM cells was used to analyze IL-23R expression by RT-PCR (**A**) and real-time PCR (**B**). *Gapdh* was used as a housekeeping gene. *Il23r* expression values were normalized to *Gapdh* expression. The relative expression of *il23r* of BM cells was arbitrarily set to 1.0. *il23r* expression was compared between the BM cells and peritoneal neutrophils. **p < 0.01. (**C**) Neutrophils were treated with 20 ng/ml IL-23 for 6 h. mRNA for *Il23r* was determined by qRT-PCR and normalized against *gapdh*. Data are reflective of three independent experiments. *p < 0.05. NT, no treatment.

mRNA expression after blockade of mTOR signaling by rapamycin. We also demonstrated a similar effect of AZD8055 on IL-23– treated neutrophils, in that both IL-17 and IL-22 transcription were dramatically inhibited (Fig. 4C). In addition, ELISA revealed that production of IL-17 and IL-22 under IL-23 stimulation was inhibited by both mTOR inhibitors, respectively (Fig. 4D). To illustrate the molecular mechanisms as to how mTOR regulates IL-17 and IL-22 production, we examined transcription of ROR γ t and AhR in the presence of mTOR inhibitors. We found that the induction of both *rorc* and *ahr* by IL-23 was inhibited by rapamycin (Fig. 4E). Similarly, AZD8055 remarkably decreased *rorc* and *ahr* mRNA expression in IL-23–treated neutrophils. Taken together, these data demonstrated that IL-23 signals through the mTOR pathway to positively regulate the production of both IL-17 and IL-22 by upregulating ROR γ t and AhR expression in neutrophils.

PI3K regulates the mTOR pathway to promote IL-17 and IL-22 production in neutrophils

PI3K has been shown to positively regulate mTOR activation (36). Based on the data that mTOR and its downstream proteins facilitate IL-23 signaling, we postulated that IL-23 regulates the mTOR pathway through induction of PI3K. As shown in Fig. 5A, IL-23 treatment enhanced the phosphorylation of PI3K in neutrophils. Addition of the PI3K antagonist LY294002 inhibited IL-23–induced

FIGURE 3. ROR γ t and AhR differentially regulate IL-17 and IL-22 production in neutrophils. (**A**) Neutrophils were treated with IL-23 (20 ng/ml) for 6 h. mRNA for *Il23r* was determined by qRT-PCR and normalized against *gapdh*. The relative expression of *rorc* and *ahr* of BM cells was arbitrarily set to 1.0, respectively. *rorc* and *ahr* expression were compared between the untreated and IL-23–treated neutrophils. *p < 0.05. (**B**) Neutrophils were treated with IL-23 (20 ng/ml), in addition to an ROR γ t inhibitor (1 μ M) and/or AhR inhibitor (3 μ M), respectively. IL-17 and IL-22 production were measured from supernatant by ELISA. Data are reflective of four independent experiments. *p < 0.05, ***p < 0.001. NT, no treatment.

driven IL-17 and IL-22 production in neutrophils. (A) Peritoneal neutrophils were treated with IL-23 (20 ng/ml) for the indicated time points. mTOR phosphorylation (Ser2448) was determined by Western blot. (B) Neutrophils were treated with IL-23 (20 ng/ml) for 1 h, in addition to rapamycin (2 µM) or AZD8055 (1 µM), respectively. Phosphorylated 4E-BP1 was detected by Western blot, with β -actin as a loading control. (C) Neutrophils were treated with IL-23 (20 ng/ml) for 6 h. mRNA for 1117 and il22 were determined by qRT-PCR and normalized against gapdh. *p < 0.05, **p < 0.01. (**D**) Neutrophils were treated with IL-23 (20 ng/ml), in the presence or absence of rapamycin (2 µM) or AZD8055 (1 µM). IL-17 and IL-22 production were measured from supernatant by ELISA. *p < 0.05, ***p < 0.001.(E) mRNA for rorc and ahr were determined by qRT-PCR and normalized against gapdh. Data are reflective of four independent experiments. *p <0.05. NT, no treatment.

PI3K phosphorylation and activation of 4E-BP1, suggesting that IL-23 activates the mTOR pathway through activation of PI3K. Moreover, treatment of neutrophils with LY294002 in the presence of IL-23 inhibited IL-17 and IL-22 production, indicating that stimulation of IL-17 and IL-22 production is mediated by the PI3K pathway (Fig. 5B, 5C). LY294002 treatment also greatly decreased the transcription level of both rorc and ahr (Fig. 5D). Notably, IL-23 treatment also led to p38 MAPK phosphorylation, which was unaffected by treatment with either mTOR or PI3K inhibitor, confirming the specific inhibition of the selected pathways without compromising neutrophil viability (data not shown). Collectively, these data indicate that IL-23 stimulates neutrophil production of IL-17 and IL-22 through the activation of the PI3K-mTOR pathway.

STAT3 has been implicated as a transcriptional regulator in T cell IL-17 and IL-22 production (37, 38). Earlier studies showed that STAT3 regulated neutrophil chemotaxis and migration (39). We then questioned whether STAT3 could also be involved in IL-23induced IL-17 and IL-22 production in neutrophils. We cultured neutrophils with IL-23 in the presence or absence of STAT3 inhibitor

FIGURE 5. PI3K regulates mTOR activation and IL-17 and IL-22 production in neutrophils. (**A**) Neutrophils were treated with IL-23 (20 ng/ml) for 1 h with or without Ly294002 (10 μ M). Phosphorylation of PI3K and 4E-BP1 were detected by Western blot, with β -actin as a loading control. (**B**) Neutrophils were treated with IL-23 (20 ng/ml) for 6 h. mRNA for *Il17* and *il22* were determined by qRT-PCR and normalized against *gapdh*. (**C**) Neutrophils were treated with IL-23 (20 ng/ml) with or without Ly294002 (10 μ M) for 24 h. IL-17 and IL-22 production were measured from supernatant by ELISA. (**D**) mRNA for *rorc* and *ahr* were detected by Western blot, with β -actin as a loading control. (**F**) Neutrophils were treated with IL-23 (20 ng/ml) with or without HJC0152 (5 μ M) for 24 h. IL-17 and IL-22 production were treated with IL-23 (20 ng/ml) for 1 h, and phosphorylation of STAT3 and NF- κ B were detected by Western blot, with β -actin as a loading control. (**F**) Neutrophils were treated with IL-23 (20 ng/ml) with or without HJC0152 (5 μ M) for 24 h. IL-17 and IL-22 production were measured from supernatant by ELISA. Data are reflective of four independent experiments. *p < 0.05, **p < 0.01. NT, no treatment.

HJC0152 (40). As expected, IL-23 was able to induce phosphorylation of STAT3, which was abrogated by HJC0152 (Fig. 5E). IL-17 and IL-22 production downstream of IL-23 signaling were reduced by addition of HJC0152 (Fig. 5F). IL-23 also activated NF- κ B in neutrophils (Fig. 5E), and addition of NF- κ B inhibitor inhibited IL-23–induced IL-17 and IL-22 (data not shown). Collectively, these data indicated that the STAT3–NF- κ B pathway also mediates IL-23 induction of IL-17 and IL-22 in neutrophils.

Neutrophils play a protective role in the pathogenesis of chronic colitis via IL-22

Thus far, our results in vitro have demonstrated the molecular mechanisms involved in the regulation of neutrophil cytokine production. We sought to determine the role of neutrophils in regulating the pathogenesis of chronic colitis. We previously established a microbiota Ag-specific model of colitis by adoptive transfer of CD4⁺ T cells from CBir1 TCR transgenic mice, which

are specific for an immunodominant microbiota Ag CBir1 flagellin, into $\operatorname{Rag}^{-/-}$ mice. The recipient mice developed colitis 4–6 wk after cell transfer (41). A neutrophil-specific, Ly6G-depleting Ab was administered i.p. twice per week to deplete neutrophils. Six weeks later, the histopathology was evaluated in large bowel (LB) and cecum. FACS staining confirmed that neutrophils were almost completely depleted in the mice administered with anti-Ly6G Ab (Supplemental Fig. 2). Overall, in the absence of neutrophils, mice presented much more severe colitis than did the neutrophil-sufficient control group (Fig. 6A), as evidenced by destroyed colon structure and loss of goblet cells. This finding corresponded to the higher pathology score of both LB and cecum in mice with neutrophil depletion (Fig. 6B). The worsened disease was also associated with significantly decreased expression of Hnf4 α , a critical regulator of tight junction proteins (42) (Fig. 6C), and increased amounts of proinflammatory cytokines in colon organ cultures (Fig. 6D). However, surface and intracellular

FIGURE 6. Neutrophils and IL-22 protect the intestines from chronic inflammation. A total of 2×10^6 CBir1 Th17 cells were i.v. transferred into Rag^{-/-} mice. (**A–C**) Recipient mice were treated with anti–Ly-6G–depleting Ab (4 mg/kg) or control mAb twice per week. At week 6 post-Th17 cell transfer, (A) H&E staining was performed on colonic histopathology of control Ab-treated mice (*left panels*) and neutrophil-depleted mice (*right panels*) for (B) blinded histological scoring. n = 4 mice/group. *p < 0.05. (C) Tissue RNA was isolated from LB. mRNA for *Hnf4a* was determined by qRT-PCR among two groups of mice and normalized against *gapdh*. *p < 0.05. (D) IL-6, IL-17, TNF- α , and IFN- γ production were measured from the supernatant of colon tissue cultures from four mice per group by ELISA. Data are one representative of three independent experiments with similar results. *p < 0.05. (**E** and **F**) CBir1 T cell recipient mice were treated with 6 mg/kg anti–IL-22 or control mAb twice per week. On week 6 post-Th17 cell transfer, H&E staining was performed and colonic histopathology of control Ab-treated mice (*left panel*) and anti–IL-22 Ab-treated mice (*right panel*), and (F) histological scores. n = 4 mice/group. Data are one representative of two independent experiments with similar results. *p < 0.01. (**G**–I) Rag^{-/-} mice were fed in drinking water with 2% DSS for 7 d, followed by 3 d of fresh water, and injected IgG control mAb, 20 mg/kg anti-Thy1.2 mAb with or (*Figure legend continues*)

staining of lamina propria cells of colitic mice revealed no significant difference of T cells in percentage and cytokine production (Supplemental Fig. 3). Collectively, these data demonstrated that neutrophils protect the intestines from chronic inflammation in response to microbiota. Because IL-22 has been shown to be an important cytokine that contributes to intestinal protection and tissue repair of the epithelial layer, we then investigated whether IL-22 protected the intestines in CBir1 T cell-mediated colitis. We administered a neutralizing Ab against IL-22 from the same day of T cell transfer and twice per week thereafter for 6 wk. As shown in Fig. 6E and 6F, blockade of IL-22 increased the severity of colitis in comparison with the mice giving control mAb. T cells and ILCs have been shown as cell sources of IL-22, in addition to neutrophils (43, 44). To elucidate the role of neutrophil-derived IL-22, independently of T cells or ILCs, we induced colitis in Rag^{-/-} mice, which do not have T cells but have intact ILC3 and neutrophils, upon DSS insult. We then depleted ILCs by giving $Rag^{-/-}$ mice anti-Thy1.2 Ab (Supplemental Fig. 4); thus, the only known resource of IL-22 will be neutrophils. Depletion of ILCs worsened the colitis in $\operatorname{Rag}^{-/-}$ mice after feeding DSS. When treated with anti-IL-22 Ab, those mice developed even more severe colitis (Fig. 6G, 6H), as well as increased intestinal permeability as evidenced by FITC-dextran migration into the serum (Fig. 6I), demonstrating that neutrophil production of IL-22 at least partially protects the mice from colitis.

Discussion

Neutrophils have been demonstrated recently to produce both IL-17 and IL-22 under various inflammatory/infectious conditions (9, 11, 19, 45). However, it is still unclear how neutrophil production of these cytokines is regulated. Also remaining unclarified is the role of neutrophils and their production of these cytokines in the pathogenesis of chronic colitis. In this study, we demonstrated that IL-23 induced neutrophil cytokine production by upregulating ROR γ t and AhR, which was mediated by the mTOR pathway. Furthermore, neutrophils protected the intestines from inflammation, possibly via the production of IL-22.

With $>10^{14}$ commensal microbiota coexisting in the gut, the host immune system uses multiple strategies to maintain intestinal homeostasis (46). Among them, neutrophils are critical components of the mucosal immune defense. The infiltration of neutrophils in chronically inflamed tissues has long been considered to exacerbate inflammation and perpetuate disease. However, recent studies have also demonstrated a beneficial effect by the accumulated neutrophils for limiting inflammation, which may outweigh their drawbacks during acute colitis (8). Consistent with these findings, we demonstrated that the depletion of neutrophils leads to more severe inflammation and exacerbated colitis during chronic intestinal inflammation, indicating a protective role for neutrophils in chronic colitis (Fig. 6A-D). In a recent genomewide association study, the gene encoding HNF4 α has been reported as a susceptibility gene for ulcerative colitis (47). Our finding that decreased expression of HNF4 α in intestines of neutrophil-depleted mice indicates that the absence of neutrophils is correlated to the enhanced gut epithelial permeability. Because neutrophils share many features with myeloid-derived suppressor cells (MDSCs), Ly6G-depleting Ab may also abolish the potential suppressive role of MDSCs, although the concept and functional

mechanisms of MDSCs are still not clear. Thus, it is warranted to investigate the functional relationship between neutrophils and MDSCs, and their relative contributions to the intestinal homeostasis.

Previous studies elaborated the protective effects of IL-22 on host bactericidal response, tissue regeneration, and wound healing. IL-22-producing neutrophils have been reported to promote antimicrobial peptide production of intestinal epithelial cells (9). Consistently, our data demonstrated a worsened chronic colitis in mice after blockade of IL-22 (Fig. 6E, 6F), indicating that neutrophils produce IL-22 as a possible way to resolve chronic colitis. T cells and ILCs have been implicated as cell sources for IL-22, in addition to neutrophils. Our data indicated that neutrophil production of IL-22 at least partially contributes to protection of the intestines from inflammation. Upon DSS insult, depletion of ILCs partially protected the Rag^{-/-} mice, which do not have T cells, from colitis (Fig. 6G-I). This could be attributed to their production of IL-22, among other possible mechanisms. Interestingly, blockade of IL-22 in ILC-depleted Rag^{-/-} mice further worsened the colitis, indicating that neutrophil-derived IL-22 protected the intestines from inflammation.

Despite the proinflammatory role of IL-17 in the pathogenesis of IBD highlighted in previous reports (3, 14), recent studies have also demonstrated a protective role of IL-17 in the maintenance of intestinal homeostasis through induction of intestinal epithelial cell expression of antimicrobial peptide and promoting intestinal IgA response against microbiota (18). The ubiquitous expression of IL-17Rs on a variety of cell types suggests that neutrophils can also "cross talk" with lymphoid, myeloid, and stromal/mesenchymal cells and exhibit effector function (48). Thus, in the intestines, IL-17 may also contribute to the protective effects of neutrophils (17). In other systems, although the beneficial role of IL-17-producing neutrophils has been demonstrated during Aspergillus fumigatus infection (11, 19), neutrophil-derived IL-17 were not detectable in certain Candida albicans infection (20), indicating that neutrophil IL-17 production may be limited to certain conditions or infections.

In agreement with previous studies (9, 49), our results showed that in response to stimulation of IL-23, but not IL-6 or other cytokines tested, neutrophils produce IL-17 and IL-22. Notably, we found a large subset of IL-22⁺ neutrophils after stimulation of IL-23 (Fig. 1C), which corresponds to large amounts of IL-22 and IL-17 in the neutrophil culture supernatant (Fig. 1A), as well as the increased expression of il22 and il17 mRNA expression (Fig. 1B). Also, a small proportion of neutrophils are also IL-10⁺. Because IL-10 is a well-established anti-inflammatory cytokine, whether these IL-10⁺ neutrophils function as regulatory cells to inhibit colitis warrants further investigation. The neutrophils are notable for their unique secretion of premade granules containing cytokines and other molecules. Indeed, a recent study reported that neutrophils release IL-17 via a neutrophil extracellular trap (50). However, the signal pathways that regulate IL-17 and IL-22 production in neutrophils remain unknown. We demonstrated that, unlike CD4⁺ T cell subtypes and ILC3, neutrophil production of IL-17 and IL-22 is strictly IL-23 dependent (Fig. 1A). Interestingly, IL-23 promotes the expression of its own receptor by neutrophils (Fig. 2), likely indicating a positive feedback to stabilize the neutrophil phenotype and contributing to

without 6 mg/kg anti–IL-22 mAb, respectively. (G) Blinded histological scoring was examined, and (H) H&E staining was performed. (I) FITC-dextran level in plasma was determined. n = 4 mice/group. Data are one representative of two independent experiments with similar results. **p < 0.01, ***p < 0.001. Scale bars, 100 µm (A and E), 50 µm (H). n.s., no significant difference.

constant IL-17 and IL-22 production. Furthermore, IL-23 induces the expression of RORγt and AhR (Fig. 3A), which differentially regulate neutrophil production of IL-17 and IL-22. Inhibition of RORγt inhibited IL-23–induced IL-17 and IL-22 production (Fig. 3B), whereas AhR inhibitor only elicited an effect on IL-22 production in neutrophils. Blockade of both RORγt and AhR signaling led to complete abrogation of IL-17 and IL-22 production. Taken together, our results indicate that neutrophils use pathways similar to that of ILC3, in that AhR synergizes with RORγt for the induction of IL-22, but not IL-17. In addition, IL-23 activates STAT3 and NF- κ B in neutrophils, which also contributed to IL-23 induction of IL-17 and IL-22.

The critical role of the PI3K/mTOR pathway has been implicated in various cellular functions (51–53). Our data indicated that the mTOR pathway mediates IL-23 induction of the neutrophil production of IL-17 and IL-22, in that IL-23 activated the mTOR pathway, and inhibition of mTOR severely compromised IL-17 and IL-22 production. It has recently been shown that mTOR induces NETosis after LPS exposure. Thus, mTOR may facilitate neutrophil cytokine production in multiple aspects.
