ECG during past 2 hours has shown frequent ventricular premature contractions and heart rates more rapid than usual - as high as 120/min. while not engaged in physical activity. VPC's are unifocal and followed by normal appearing complexes. More recent records have shown supraventricular (atrial) premature contractions with periods of bigeminal rhythm. Significance of both is probably the same and most likely associated with fatigue. Has been observed to have similar VPC's during chamber monitoring. Sedation and rest should help the situation but probably not before several hours have elapsed.
